KENTUCKY audious FORESTS

Southern Cumberland Unit

FOREWORD

More than a decade has elapsed since the last comprehensive inventory of Kentucky's woodlands. Timber cutting, tree growth, and shifts in land use since then have led to several important changes in the timber resource. The demand for forest products has also changed. So, there is an urgent need for new information. Recent emphasis on rural-area development has made the necessity for fresh statistics even more pressing. Local communities and forest-based industries are finding a greater need for up-to-date data as they plan for future economic development.

To meet these needs, the Division of Forestry of the Kentucky Department of Natural Resources and the U.S. Forest Service planned and conducted a new inventory of Kentucky forests. The field work was completed in 1964.

The McSweeney-McNary Forest Research Act of 1928 authorizes the Forest Service to complete a statewide forest inventory of Kentucky at approximate 10-year intervals. This is part of the nationwide program of maintaining a current account of our timber resources. The State of Kentucky appropriated \$120,000 for the current survey. This contribution, supplementing the Federal funds available for a regular survey, made it possible to intensify the inventory. As a result, we can provide the kind of detailed information needed for making long-range plans to meet future demands and in addition help local communities and forest-based industries make more efficient use of the forest resource.

The resurvey was conducted by the Lake States Forest Experiment Station and the Kentucky Division of Forestry. Clarence D. Chase, Leader of the Survey Project at the Lake States Forest Experiment Station, directed the work. Timber growth, cut, and inventory data were compiled by the Lake States Survey Unit. Scientists of the Central States Forest Experiment Station took part in planning the survey, training the field crews, and compiling and analyzing the data.

Personnel of the Eastern Region of the U.S. Forest Service inventoried and provided statistics for the Cumberland National Forest. The Northeastern Forest Experiment Station assisted with the computation of National Forest data. The Tennessee Valley Authority provided men and equipment to assist in surveying areas of their interest. The Soil Conservation Service and the Agricultural Stabilization and Conservation Service provided the field crews with office space and up-to-date aerial photography. The Kentucky Department of Highways took and provided aerial photographs for parts of eastern Kentucky where no recent photography was available. The University of Kentucky and Kentucky Department of Commerce took an active part in planning and gave valuable assistance with problems that evolved during the course of the inventory. Our thanks go to all these organizations and others who contributed.

For sampling and reporting purposes, the State was divided into seven survey units (frontispiece). This report covers the Southern Cumberland Unit. Additional information regarding the survey can be obtained from either the Division of Forestry, Kentucky Department of Natural Resources, or the Central States Forest Experiment Station.

THE TIMBER RESOURCE HAS CHANGED

The Southern Cumberland Unit is a heavily forested, 12-county area located in Southeastern Kentucky. There are 2.2 million acres of forest in the Unit, 5 percent more than at the time of the last survey in 1949. Much of the gain in forest area can be attributed to a declining agriculture. U.S. Bureau of the Census data indicate a sharp decrease in both the number of farms and farm acreage in the region between 1949 and 1959. Many submarginal farms were abandoned and idle fields and pastures taken over by tree seedlings (fig. 1).

Less than 1 percent of the forest is classified noncommercial, i.e., either too poor for timber production or reserved from cutting. Commercial-forest land increased in nearly every county of the region (fig. 2). Today more than 79 percent of the land area is producing timber and the woodland is well distributed. No county is less than two-thirds forested. Hardwoods predominate on more than 90 percent of the forest area. The principal forest types are oak-hickory and central mixed hardwoods. About half the forest area is in sawtimber stands; most of the remainder is equally divided between the poletimber and seedling-sapling sizes. Less than 1 percent is nonstocked.

FIGURE 1.— Many abandoned fields and pastures have reverted to forest since the last survey.

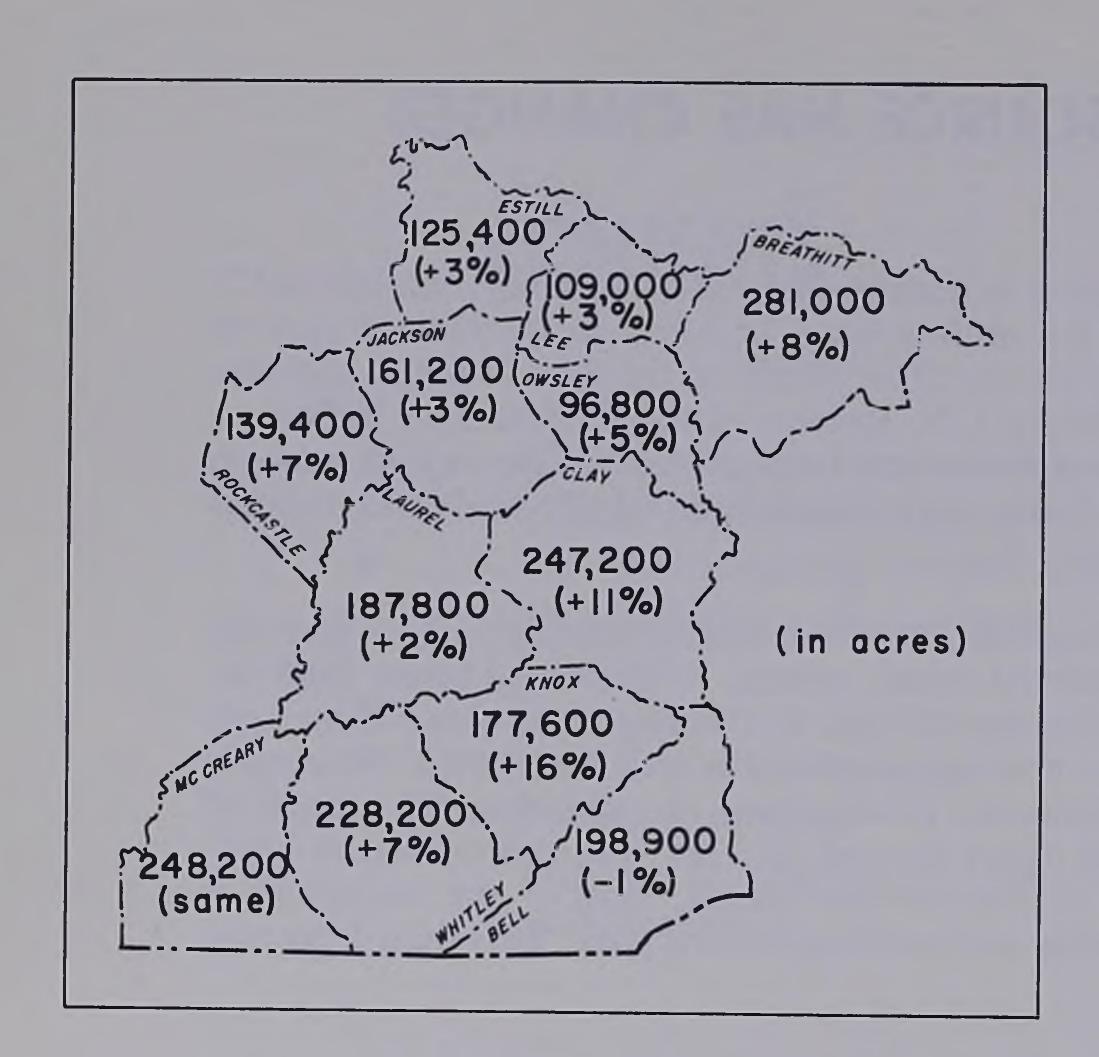

FIGURE 2.— Area of commercial-forest land by county, 1963, and percentage change since 1949.

FIGURE 3. — Change in volume of growing stock by diameter class, 1949-1963.

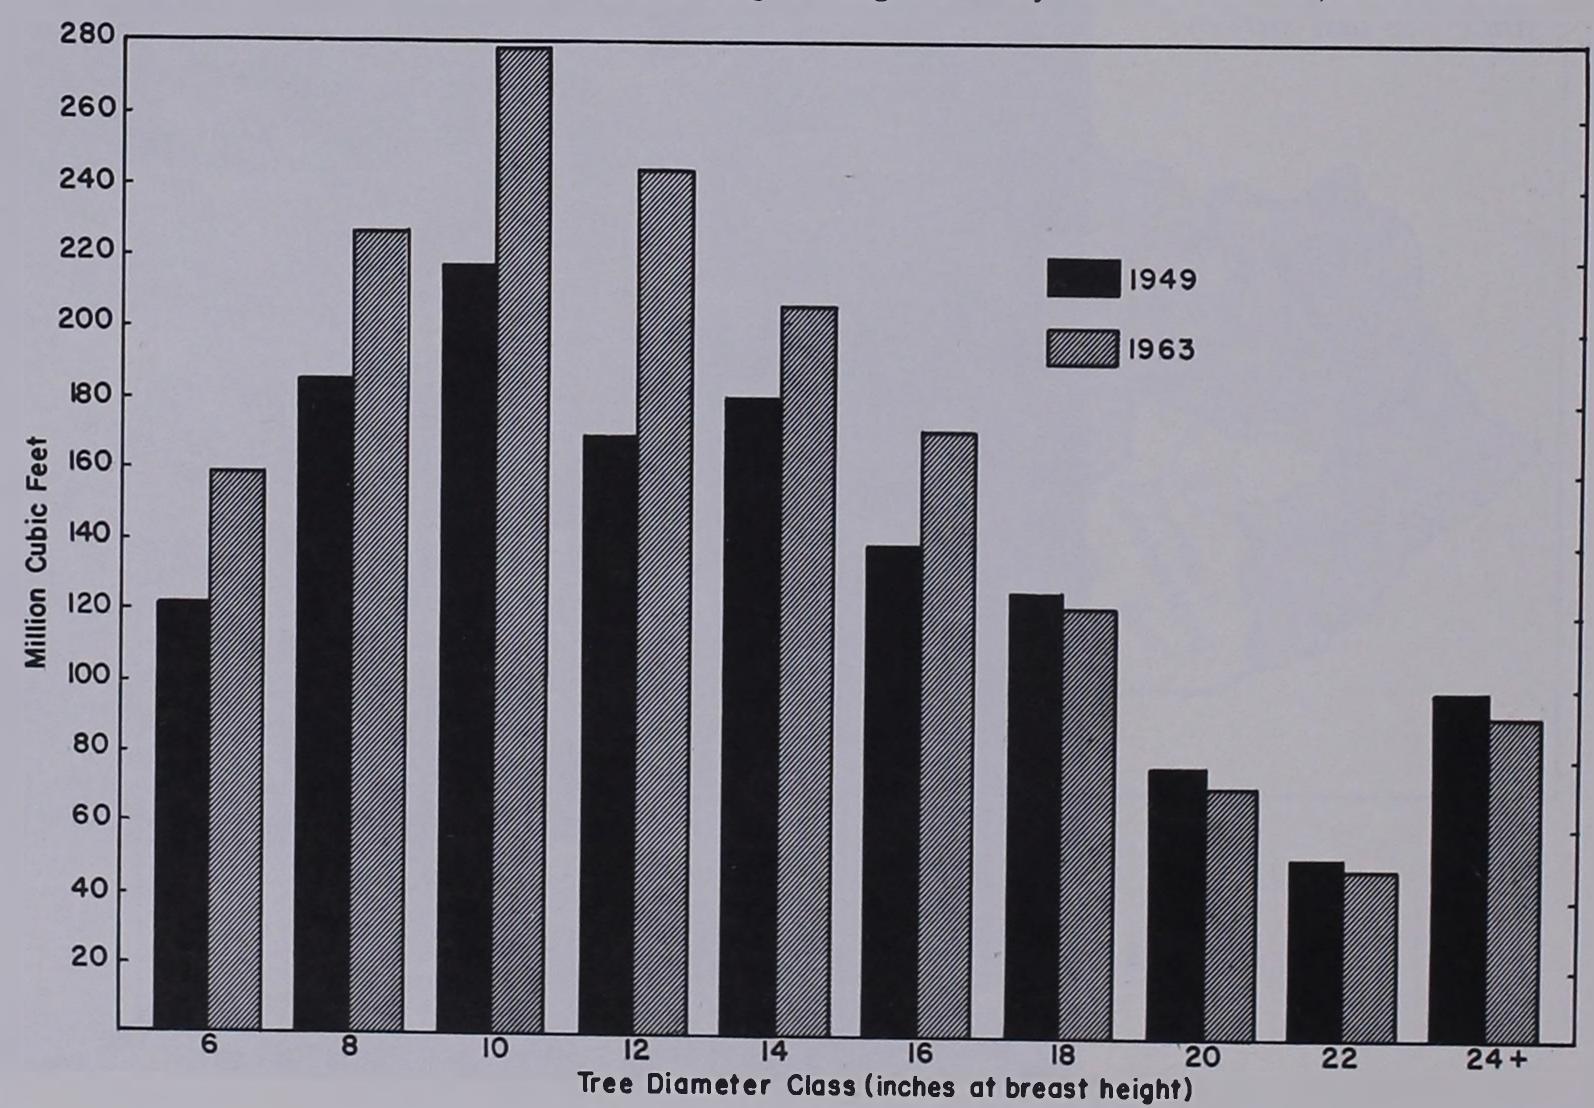

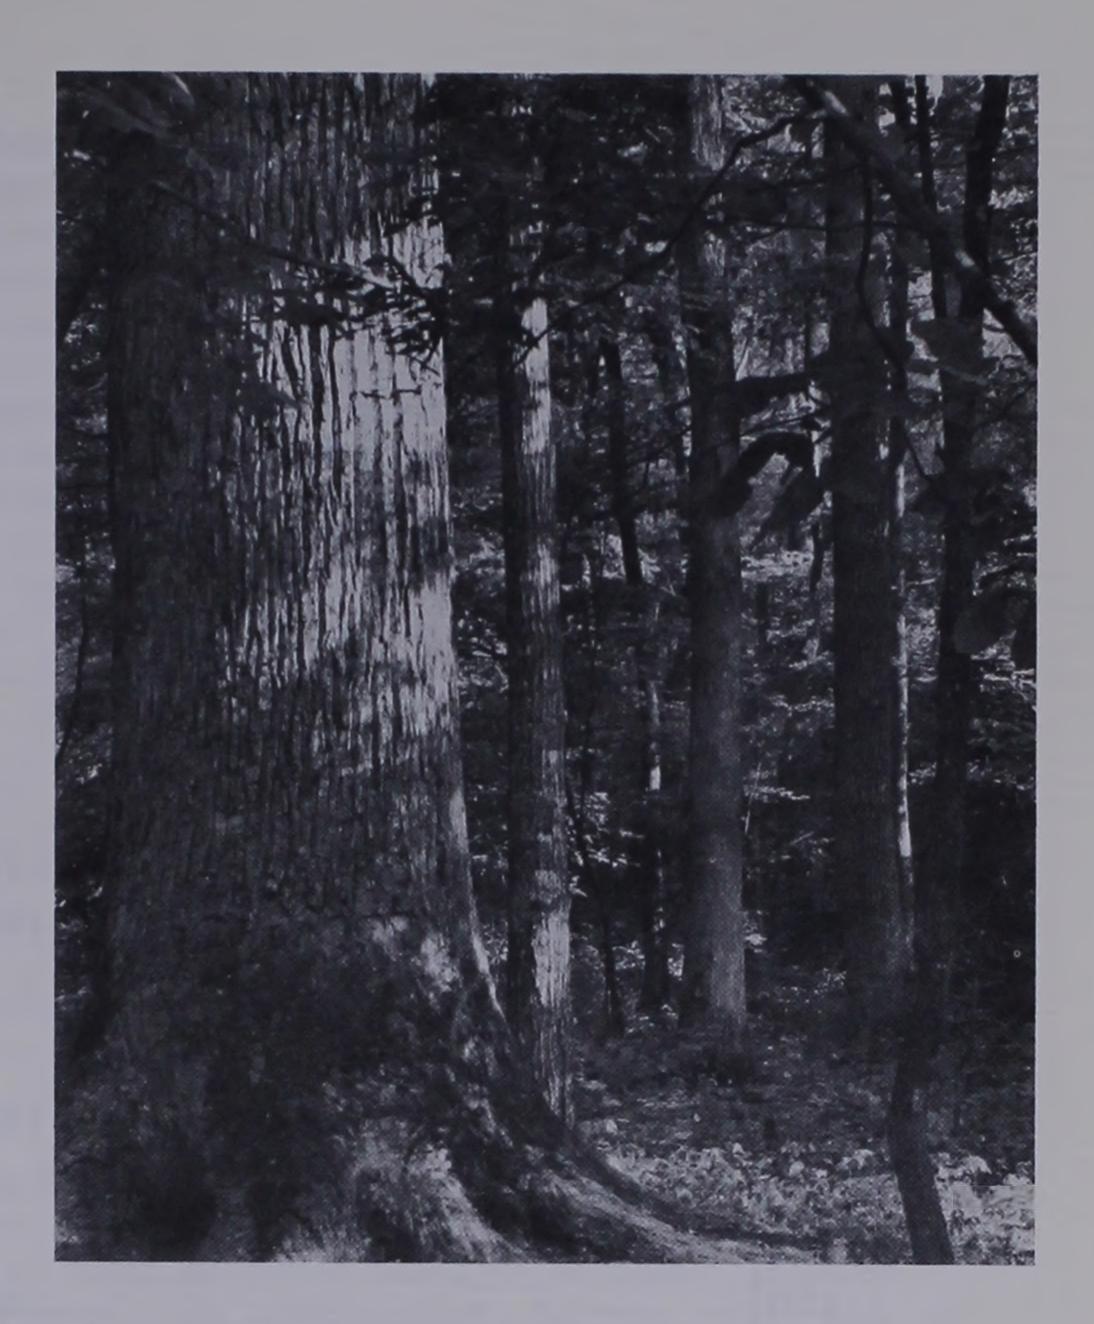

FIGURE 4. — High-quality timber such as this is becoming scarce.

The volume of merchantable timber also increased by about one-fifth to 1.6 billion cubic feet between inventories. This amounted to an average increase of more than 80 cubic feet per acre. However, most of the increase was in small trees (fig. 3). The volume of large, high-quality timber, preferred by most of the local sawmills, cooperage mills, and other primary-wood-using industries, has declined. As a result, there has been a significant shift in the distribution of timber volume by size classes. In 1949, about 75 percent of the growing stock was in trees less than 17 inches d.b.h. Now 80 percent is in this size.

There has been a similar change in the size distribution of sawtimber. Sawtimber volume as a whole increased 4 percent between surveys. The volume of saw-log material in trees less than 17 inches d.b.h. increased 15 percent. But the volume in larger trees decreased 11 percent indicating there are fewer large, high-grade saw logs now than in 1949 (fig. 4).

However, the large increase in small, sound growing stock has increased the quality-growth potential of the timber base. Large numbers of poletimber trees are now reaching sawtimber size and about half of the present sawtimber volume is in trees less than 15 inches d.b.h. As these trees mature during the next few decades, there should be a healthy increase in large, high-quality saw logs.

¹The 1949 estimates of growing-stock volume are not directly comparable with those of 1963 because they did not include merchantable material in the upper-stem portion of hardwood sawtimber-size trees. The 1949 data had to be adjusted to permit comparisons.

The species composition of Southern Cumberland forests has also changed (figs. 5 and 6). Probably most startling is the large decrease in sawtimber volume of shortleaf pine, one of the region's most important timber species. The numbers of and volume in small shortleaf pine trees (less than 11 inches d.b.h.) increased greatly between surveys. But this increase was more than offset by cutting and mortality in larger timber. The end result was a 36-percent decline in sawtimber volume and a 2-percent decline in all shortleaf pine growing stock between surveys. The volume of other yellow pines (mainly Virginia and pitch) increased and these species now account for more than one-third of the region's softwood volume.

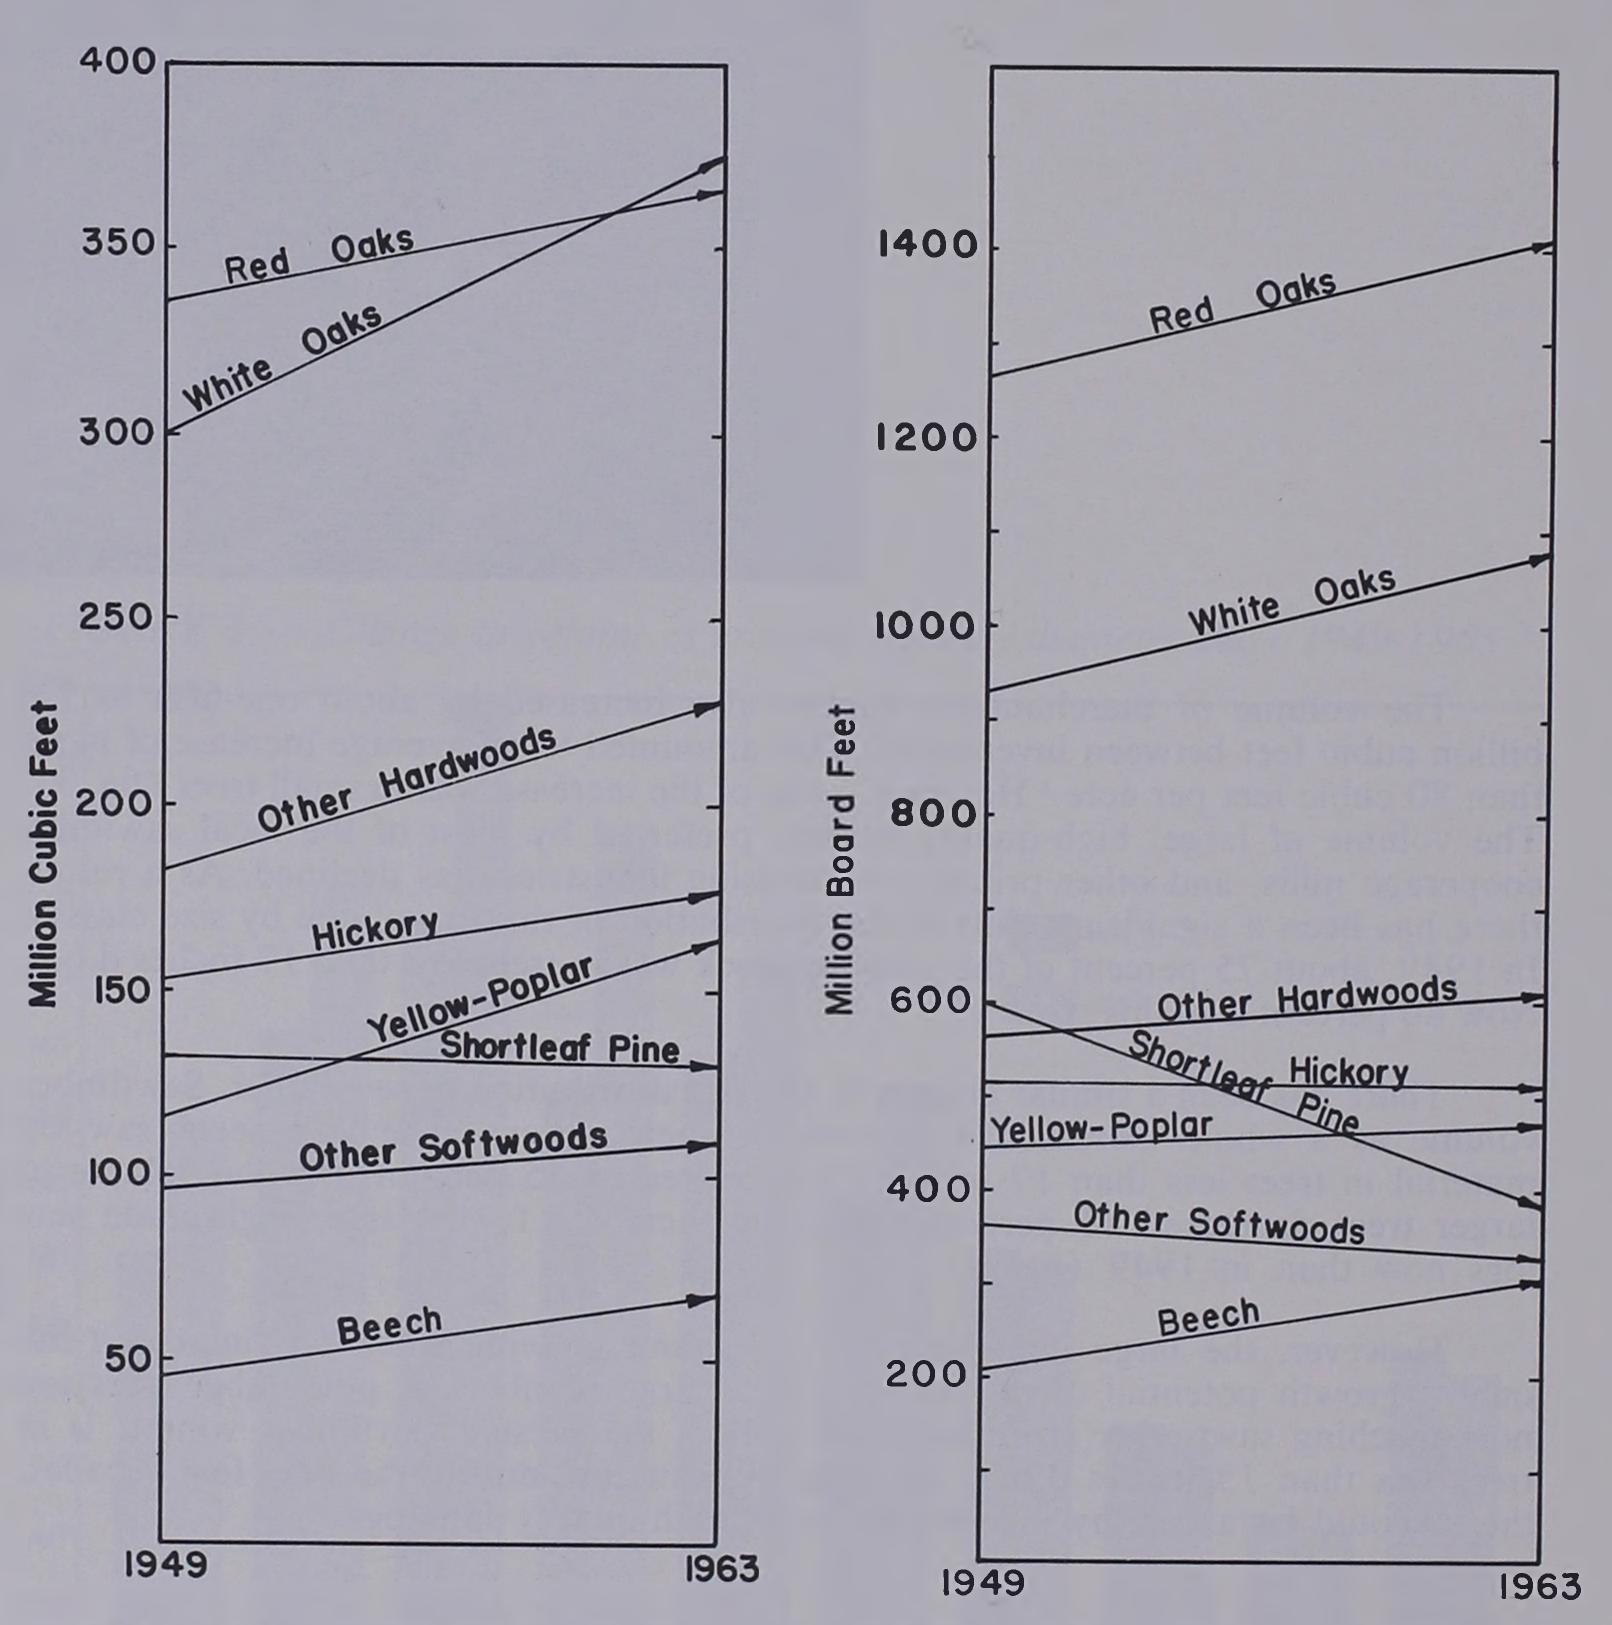

FIGURE 5.— Change in growingstock volume by species groups, 1949-1963.

FIGURE 6.— Change in sawtimber volume by species groups, 1949-1963.

Most hardwood species showed large volume gains in small trees, but changes in large-hardwood volumes varied. The sawtimber volume of oak, yellow-poplar, beech, and maple (all heavily used species) increased. But the saw-log volume of some other important species, such as black walnut, basswood, and ash, declined sharply. Oak species now contain about half of the region's sawtimber volume.

Just as important as knowing how much and what kind of timber we have, is knowing who owns it because ownership largely determines availability as well as protection and management of the resource. About four-fifths of the region's timber is in the hands of farmers, forest industries, and other private owners. Most of the remainder is on the Cumberland National Forest. Stocking is much greater on the National Forest than on other land. Even though the National Forest includes less than 14 percent of the commercial-forest land in the region, it contains more than 22 percent of the growing stock.

TIMBER INDUSTRIES AND DRAIN

Almost 17 million cubic feet of growing stock were cut from the Southern Cumberland Unit in 1962. This was 14 percent of the total cut in Kentucky during the year.

Some 100 primary-wood-using firms are located in the region (fig. 7). Most of them are sawmills and only a dozen or so produce more than a million board feet annually. In 1962 the region produced about 70 million board feet of lumber. Included among the Region's other primary-wood-using establishments are one veneer mill,

FIGURE 7.—Location of primary-wood-using industries, 1963.

four stave mills, and two handle plants. The wood used by these other plants represents a small drain on the timber resource. But they use high-quality logs and bolts of preferred species such as walnut, white oak, yellow-poplar, and ash. Supplies of this valuable timber are scarce.

Although the region has no pulpmills, the cut of pulpwood has been increasing in recent years. In 1964, a total of 74,000 tons of pulpwood was harvested from the Southern Cumberland Unit. Most of it was pine that was shipped to mills in southern states.

A lion's share of the cut in 1962 was from trees of sawtimber size. The harvest of sawtimber amounted to almost 91 million board feet — 40 percent of it oak. Following in order of importance were yellow-poplar, beech, shortleaf pine, and hickory. More than a third of the poletimber volume cut was shortleaf pine which was used mainly for pulpwood and fenceposts.

THE CURRENT BALANCE BETWEEN GROWTH AND CUT

In 1963, the net annual growth of growing stock in the Southern Cumberland Unit was 71 million cubic feet or 4.4 percent before allowances are made for cutting. This amounts to an average growth of 32 cubic feet per acre per year. Sawtimber volume was growing at a rate of 324 million board feet or 6.4 percent per year. The above volume-growth rates are well below the potential of the region's forests. Ninetenths of the timberland has the capacity to produce in excess of 50 cubic feet per acre per year and more than half of it, the capacity to produce more than 85 cubic feet per acre per year (potential expressed in terms of mean annual growth at culmination of increment in fully stocked stands of desirable trees).

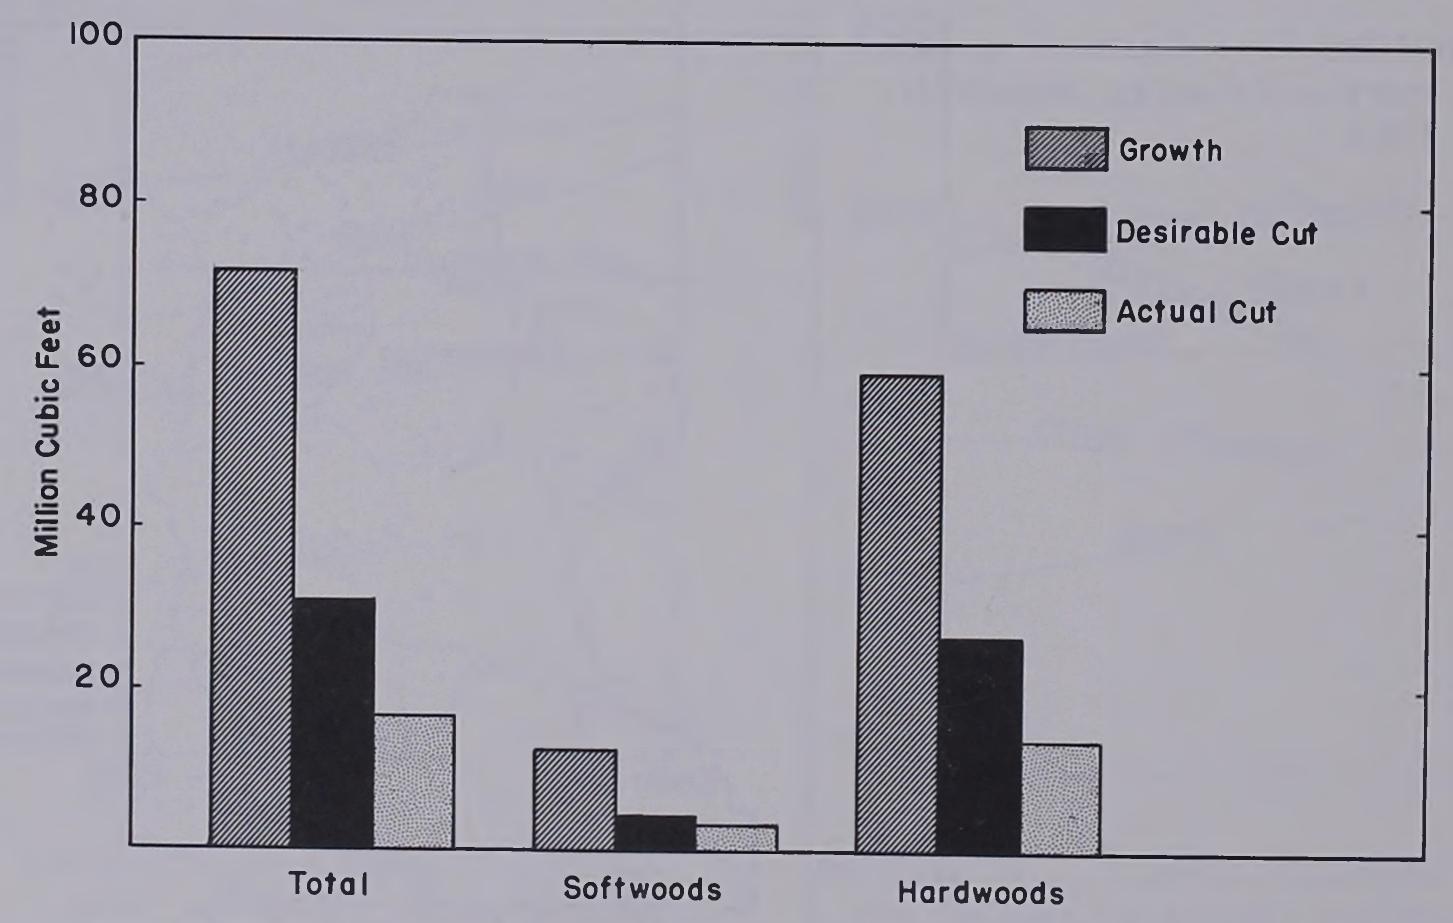

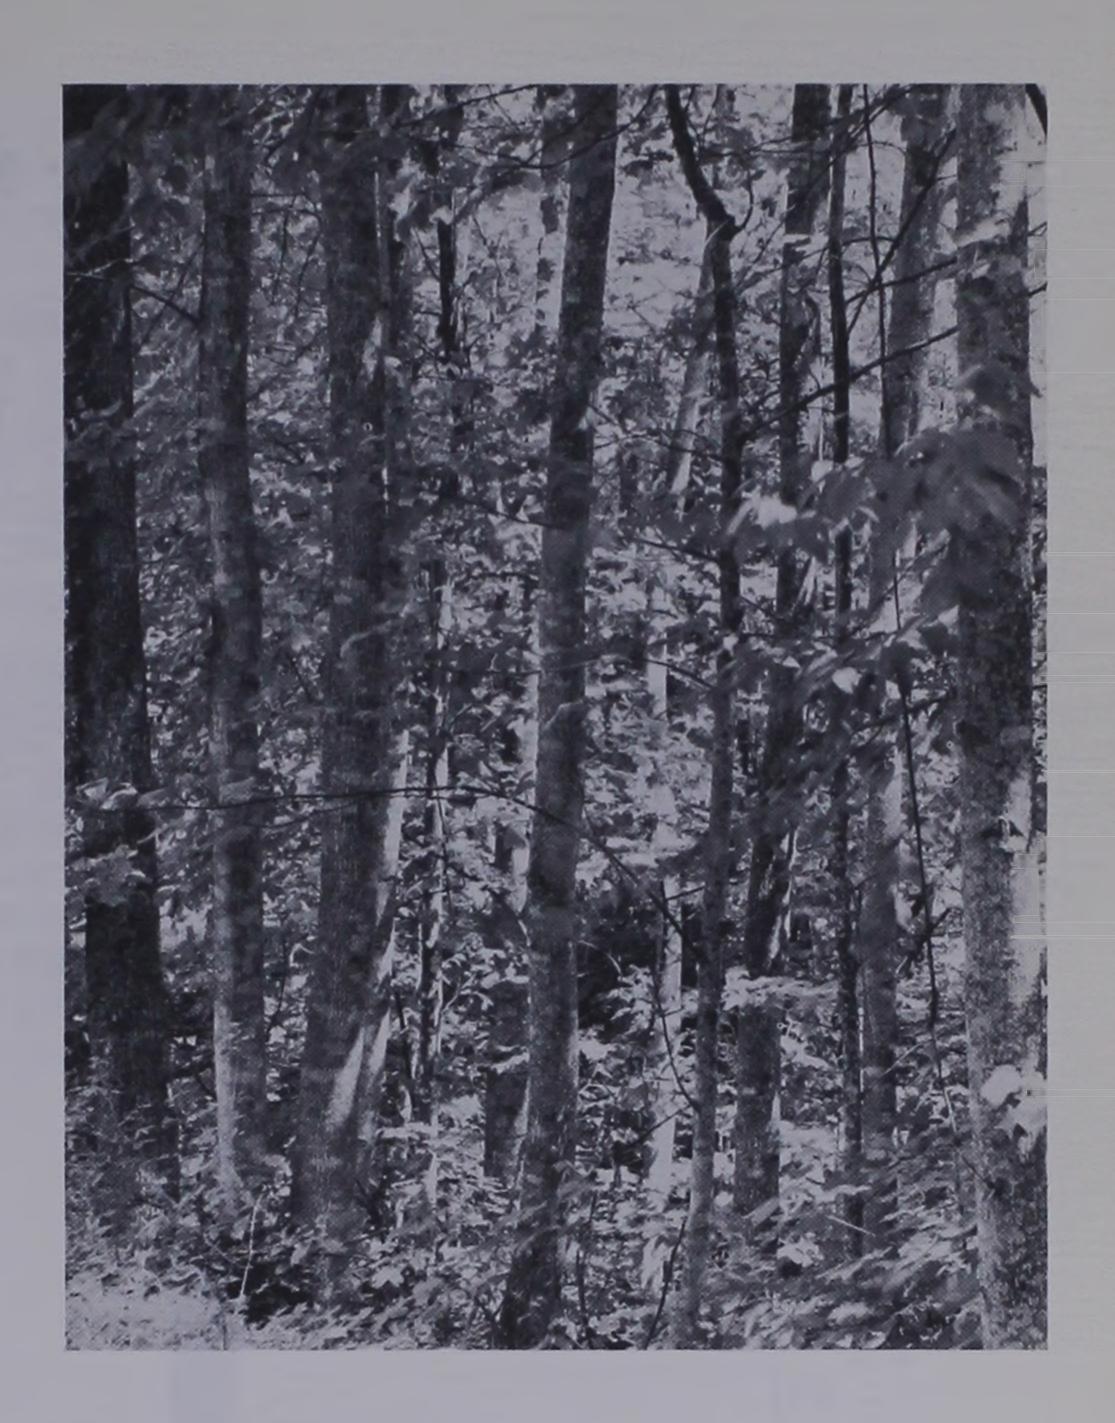

FIGURE 8. — Growth, desirable cut, and actual cut of growing stock by major species groups, 1963.

FIGURE 9.— Part of the everincreasing surplus of small, sound growing stock.

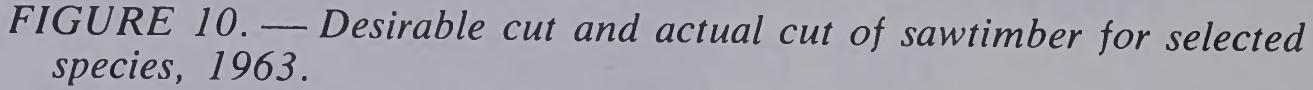

Large increases in productivity and quality growth will not take place until stocking is improved. Poor growing stock and culls are occupying space that could be growing thrifty crop trees. At present only 45 percent of the forest is well stocked with merchantable or potentially merchantable trees. And only 20 percent is in a highly productive condition, i.e., well stocked with desirable trees or expected to attain this stocking without treatment in the near future. An average of one out of every seven live trees of merchantable size (5 inches d.b.h. and larger) is a cull.

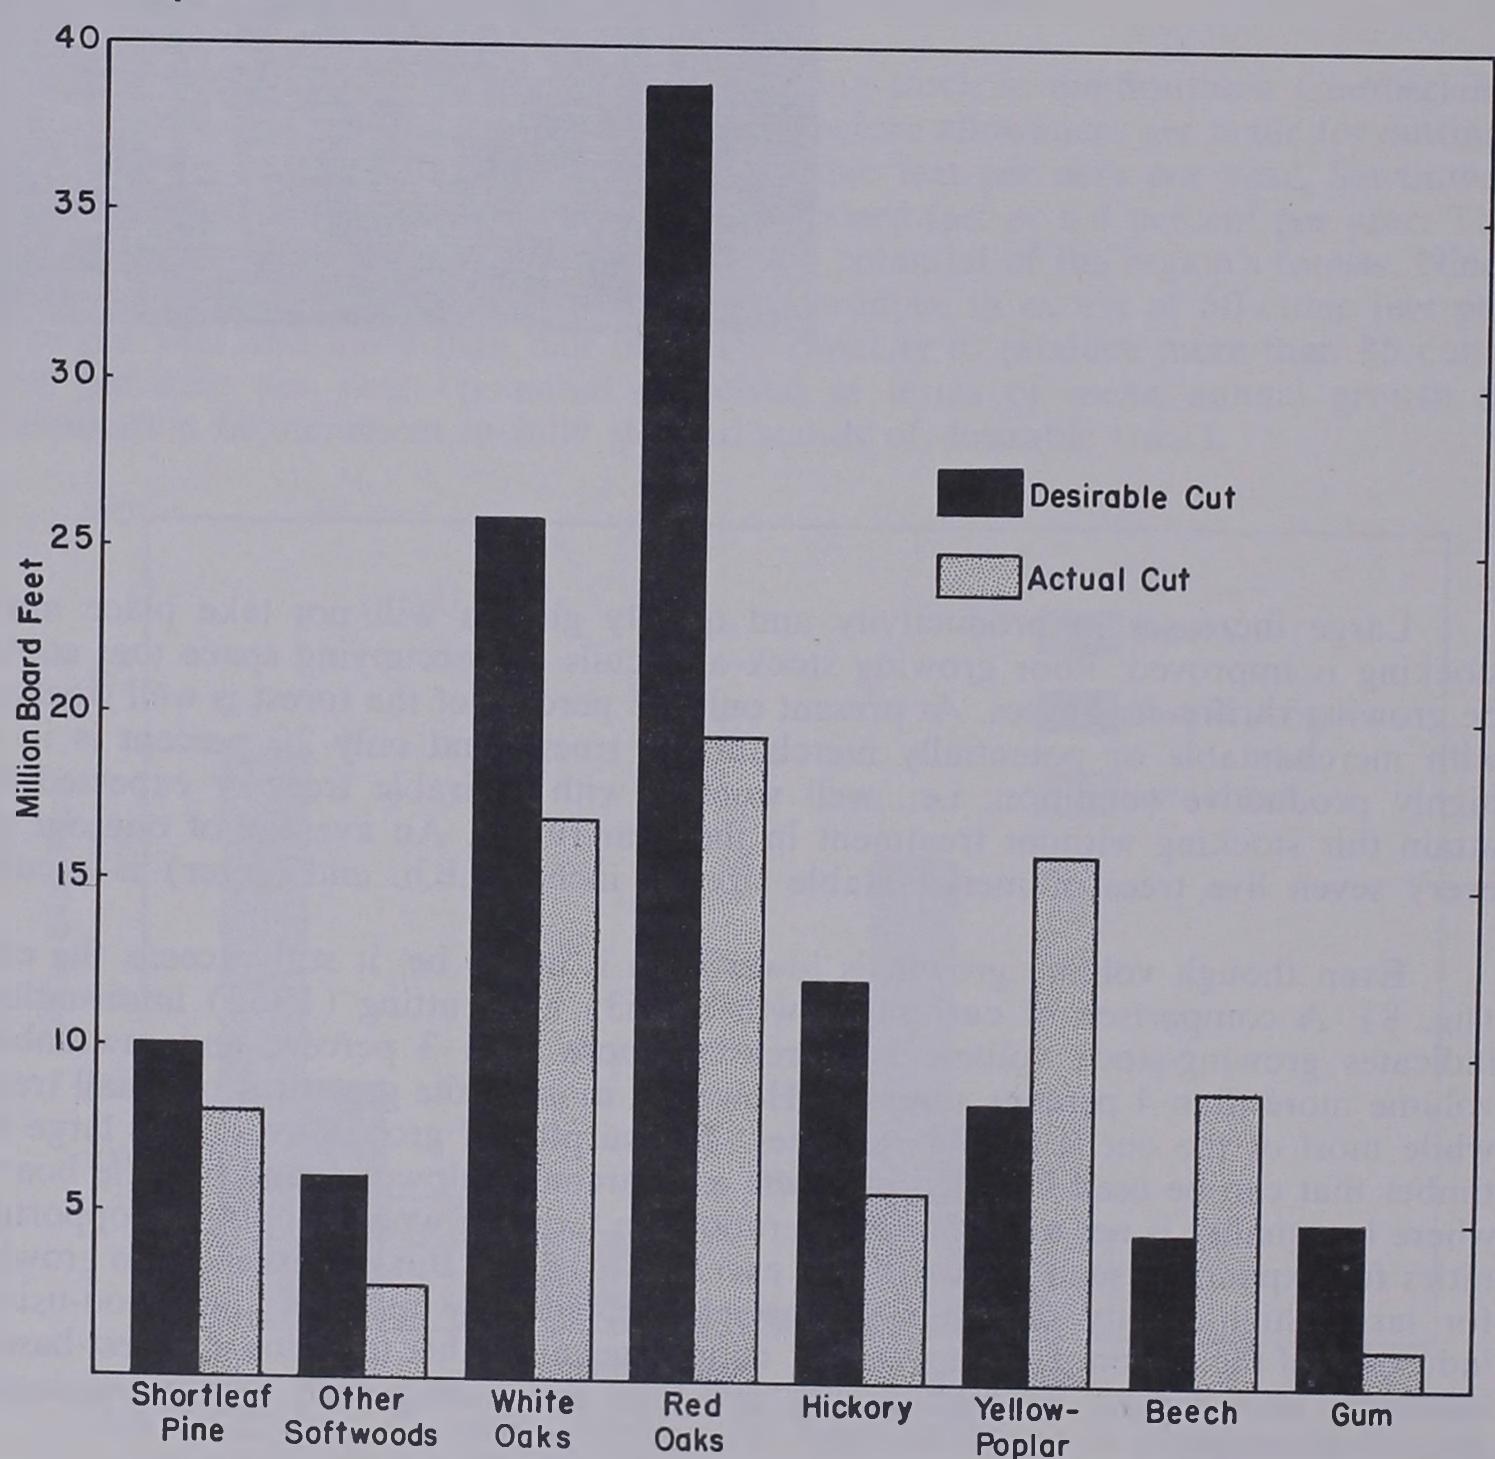

Even though volume growth is lower than it might be, it still exceeds the cut (fig. 8). A comparison of current growth (1963) and cutting (1962) information indicates growing-stock volume is increasing more than 3 percent and sawtimber volume more than 4 percent annually. However, most of the growth is on small trees while most of the cut is from large trees. The surplus of growth over cut is large in timber that can be used for such products as charcoal, pulpwood, and particle board where log quality is not a major consideration. In terms of wood supply, the opportunities for expanding such industries are excellent (fig. 9). But cut exceeds the growth for large, high-quality saw logs of species preferred by most of the wood-using industries of the region. Lumber-veneer, cooperage, and other traditional, forest-based industries that depend on high-quality saw logs are finding such logs increasingly difficult to obtain.

MORE TIMBER CAN BE HARVESTED

We have estimated the volume of merchantable timber that can be cut annually during the next decade and still maintain a healthy balance of age classes and improve the productivity of the region's forests. This is known as the "desirable cut." It includes harvest cuts from maturing stands, commercial thinnings from overstocked stands, and emergency cuts from overmature stands. The primary goal of the desirable cut is to establish a regulated forest producing a sustained yield of timber. When this is achieved, the desirable cut will be exactly equal to growth.

The desirable cut, then, is calculated chiefly from a silvicultural viewpoint—what is good for the stand in the longrun. Such long-range silvicultural goals may not always be compatible with those of forest industries that must consider current profits or those of small communities striving for rapid economic development.

Though theoretical, the desirable cut has practical application. It provides a standard that can be compared with actual cutting to indicate where shortages and surpluses occur in the timber supply. If the growth of a particular kind of timber exceeds the actual cut, it does not necessarily follow that the desirable cut will also exceed the actual cut. For example, it may be silviculturally desirable to hold back cutting until this timber reaches a larger size. Nor can we always expect the desirable cut to be less than the actual cut merely because growth is less than the actual cut. It is possible that a large amount of cutting is needed to salvage maturing or overmature timber. This could increase the desirable cut greatly.

The desirable cut of growing stock for the Southern Cumberland Unit is estimated at 31 million cubic feet annually. This exceeds the current cutting rate by some 14 million cubic feet, a surplus that could support several new wood-using establishments (fig. 8). But the excess of desirable cut is not the same for all species and sizes of timber. The desirable cut of poletimber volume is almost three times the actual cut. New outlets for this small-sized timber would have to be found to make the desirable cut a commercial undertaking. The desirable cut of sawtimber also exceeds the actual cut but by a lesser amount. For many important timber species such as yellow-poplar, beech, black walnut, and the select oaks, the desirable cut of sawtimber is less than the actual cut (fig. 10). The deficit is greater in large-diameter classes where high quality is concentrated.

APPENDIX

Forest Survey Procedure

The resource statistics presented in this report were obtained from two sources: a timber-management-plan forest inventory of the Cumberland National Forest and a survey of all other forest land. Both were sampling surveys designed to yield reliable statistics for large areas. Both combined aerial photo interpretation and field work to minimize costs. Both employed electronic, data-processing machines to reduce computing time and generate more usable statistics than could be done by hand methods.

To attain specific levels of statistical accuracy, triple sampling was used. A large number of points were first examined on aerial photographs to determine the proportions of forest and nonforest land. One-fourth of the forest points were stereoscopically classified as to forest type, stand size, stocking, and site. One-twelfth of these points were in turn examined on the ground. The ground classification provided a check on photo classification and a means of improving estimates of forest area.

At each forest ground-check point a plot was established. Trees were classified and measured as a basis for estimating timber volume, growth, mortality, and quality. Ownership was determined for each plot.

Timber-cut information was based on forest-industry production records for 1962, on stump counts at forest-inventory plots, cutting records from large owners, and utilization factors based on a logging-residue study.

Accuracy of Survey Estimate

Estimates of forest area and timber volume are subject to two kinds of errors: (1) nonsampling errors caused by mistakes in judgment, recording of measurements, or in calculations, and (2) sampling errors inherent in statistical work.

Nonsampling errors are not measurable and cannot be shown. They are avoided as much as possible through training of personnel, close supervision, and careful checking of all phases of the work.

Sampling errors are subject to the laws of chance and may be estimated by statistical methods. These errors are held to acceptable levels commensurate with the values involved and funds available by adjusting the survey design and the intensity of the sample. With a probability of two out of three (that is, relatively good) the accompanying table shows the accuracy of the data presented in this report. The sampling error of a survey is less for a large class or block than for a smaller class or other subdivision. Some of the resource statistics presented in this report have such large errors that it would be unwise to use them alone — but if they are combined with other figures the error may be reduced enough to warrant their use. Weak figures are shown to allow various combinations of data.

| Commercial- forest land | Standard error of sampling | Growing-stock volumes | Standard error of sampling | Sawtimber volumes | Standard error of sampling |
|----------------------------|----------------------------|--------------------------|----------------------------|----------------------|----------------------------|
| Acres | Percent | Thousand cubic feet | Percent | Thousand board feet | Percent |

Definition of Terms

Land and Forest Area

Gross area. — The entire area of land and water as determined by the Census Bureau.

Land area. — The area of dry land and land temporarily or partially covered by water such as marshes, swamps, and flood plains, streams, and sloughs less than 1/8 mile wide; and lakes, reservoirs, and ponds less than 40 acres in area.

Forest land. — Land at least 10 percent stocked by forest trees of any size, or formerly having such tree cover and not currently developed for nonforest use. Does not include urban or thickly settled residential and resort areas, city parks, orchards, farmsteads, improved roads, or land developed and maintained for nonforest use by fencing, seeding, and so forth. The minimum area for classification of forest land or classes of forest land was 1 acre. Roadside, streamside, and shelterbelt strips of timber having a crown width of at least 120 feet qualified as forest land. Unimproved roads and trails, streams, and clearings in forest land were included as forest if less than 120 feet wide.

Commercial-forest land. — Forest land that is producing or capable of producing crops of industrial wood and not withdrawn from timber utilization by statute or administrative regulation.

Noncommercial-forest land. — Unproductive forest land incapable of yielding crops of industrial wood because of adverse site conditions; and productive, public-forest land withdrawn from commercial timber use through statute or administrative regulation.

Ownership

National Forest. — Federal land that has been designated by Executive order or statute as National Forest, including purchase units; and other land under the administration of the Forest Service, including experimental areas and Bankhead-Jones Title III land.

Other public. — All publicly owned land other than National Forest.

Forest industry. — Land owned by companies or individuals operating wood-using plants.

Farmer and miscellaneous private. — All privately owned land except forest industry land.

Forest Types

Forest type. — A classification of forest land based upon species composition considering all live trees.

Southern pine. — Forests in which 50 percent or more of the stocking is short-leaf or other southern yellow pines, singly or in combination.

Redcedar-hardwoods. — Forests in which 50 percent or more of the stocking is hardwoods but in which redcedar makes up at least 25 percent of the stocking. Included also are those areas where redcedar makes up most of the stocking.

Oak-pine. — Forests in which 50 percent or more of the stocking is hardwoods (usually upland oaks) but in which southern pine makes up at least 25 percent of the stocking.

White oak. — Forests in which 50 percent or more of the stocking is white oak, except stands that classify as redcedar-hardwoods or oak-pine.

Oak-hickory. — Forests in which 50 percent or more of the stocking is upland oaks or hickories, singly or in combination, except stands that classify as oak-pine, redcedar-hardwoods, or white oak.

Central mixed hardwoods. — Forests in which 50 percent or more of the stocking is a combination of hardwood species, principally yellow-poplar, maple, beech, basswood, black walnut, elm, and northern red oak, except stands that classify as redcedar-hardwoods, oak-pine, oak-hickory, maple-beech, or elm-ash-cottonwood.

Maple-beech. — Forests in which 50 percent or more of the stocking is maple or beech, singly or in combination, except stands that classify as redcedar-hardwoods or oak-pine.

Elm-ash-cottonwood. — Forests in which 50 percent or more of the stocking is elm, ash, or cottonwood, singly or in combination except stands that classify as redcedar-hardwoods or oak-pine.

Stand-Size Classes

Stand-size class. — A classification of forest land based on the predominant size of timber present; sawtimber, poletimber, or seedlings and saplings.

Sawtimber stands. — Stands at least 10 percent stocked with growing-stock trees, with half or more of this stocking in sawtimber or poletimber trees and with sawtimber stocking at least equal to poletimber stocking.

Poletimber stands. — Stands at least 10 percent stocked with growing-stock trees, and with half or more of this stocking in sawtimber and/or poletimber trees and with poletimber stocking exceeding that of sawtimber.

Seedling-sapling stands. — Stands at least 10 percent stocked with growing-stock trees and with seedlings and/or saplings comprising more than half of this stocking.

Nonstocked areas. — Commercial-forest land less than 10 percent stocked with growing-stock trees.

Stocking Classes

Stocking class. — A classification of commercial-forest land based on the percent of area occupied by growing-stock trees.

Well stocked. — Stands that are 70 percent or more stocked with present or potential growing-stock trees.

Medium stocked. — Stands that are 40 to 69 percent stocked with present or potential growing-stock trees.

Poorly stocked. — Stands that are from 10 to 39 percent stocked with present or potential growing-stock trees.

Nonstocked. — Areas of commercial forest land not qualifying as sawtimber, poletimber, or seedling and sapling stands. These areas may contain some volume but less than 10 percent of the growing space is effectively utilized by growing stock.

Area-Condition Classes

A classification of commercial-forest land based upon stocking by desirable growing-stock trees and conditions affecting current and prospective timber growth. Desirable growing-stock trees are those that have no serious defects in quality limiting present or prospective use. They have relatively high vigor and contain no pathogens that may result in death or serious deterioration before rotation age. These are the trees that would be favored in silvicultural operations.

Desirable. — Areas 70 percent or more stocked with desirable trees.

Moderate and favorable. — Areas 40 to 70 percent stocked with desirable trees and with 30 percent or less of the area having other trees and/or inhibiting vegetation or surface conditions that will prevent occupancy by desirable trees.

Moderate and unfavorable. — Areas 40 to 70 percent stocked with desirable trees and with more than 30 percent of the area having other trees and/or inhibiting vegetation or surface conditions that will prevent occupancy by desirable trees.

Poor but favorable. — Areas less than 40 percent stocked with desirable trees and with 30 percent or less of the area having other trees and/or inhibiting vegetation or surface conditions that prevent occupancy by desirable trees.

Poor and unfavorable. — Areas less than 40 percent stocked with desirable trees and with more than 30 percent of the area having other trees and/or inhibiting vegetation or surface conditions that prevent occupancy by desirable species.

Volume Classification

Growing-stock volume. — Cubic-foot volume of sound wood in the bole of sawtimber and poletimber trees from the stump to a minimum 4-inch-top diameter outside bark or to the point where the central stem breaks into limbs.

Sawtimber volume. — Net volume of the saw-log portion of live sawtimber trees in board feet, International ¼-inch rule. The saw-log portion extends from stump to a minimum top diameter outside bark of 6 inches for softwoods and 8 inches for hardwoods or to the point where defects reduce saw-log quality below Standard Log Grade 3 or Tie-and-Timber Grade.

Tree-Size Classes

Sawtimber trees. — Live trees of commercial species containing at least an 8-foot saw log. Softwoods must be at least 9 inches and hardwoods at least 11 inches d.b.h. outside bark.

Poletimber trees. — Live trees of commercial species at least 5 inches d.b.h. but smaller than sawtimber size, and of good form and vigor.

Saplings. — Live trees of commercial species 1 to 5 inches d.b.h. and of good form and vigor.

Seedlings. — Live trees of commercial species less than 1 inch d.b.h. that are expected to survive.

Growth

Net annual growth. — The annual change in volume of sound wood in live sawtimber and poletimber trees and the total volume of trees entering these classes through ingrowth less volume losses resulting from natural causes on commercial-forest land.

Growing-stock growth. — Net annual growth of pole and sawtimber trees in cubic feet.

Sawtimber growth. — Net annual growth of sawtimber trees in board feet, International ¼-inch rule.

Timber Cut

Timber cut from growing stock. — The net cubic-foot volume of sound wood in live sawtimber and poletimber trees cut for forest products during a specified year, including both roundwood products and logging residues.

Timber cut from sawtimber. — The net board-foot volume of live sawtimber trees cut for forest products during a specified year, including both roundwood products and logging residues.

Desirable cut (formerly called allowable cut). — The net volume of live saw-timber and poletimber trees that can be cut annually during the next 10 years in commercial-logging operations while maintaining or increasing growing stock and while effecting a reasonably even distribution of age classes below the rotation age selected for each type. It includes harvest and improvement cuts yielding 3 cords or more per acre, and one-tenth of the entire net volume of stands 10 or more years beyond the rotation age. Desirable cut includes all timber of merchantable size that should be cut from commercial-forest land in order to salvage, rejuvenate, or improve the stands and increase the growth without regard to restraints of ownership, inaccessability, or the profit motive. Some of this timber may not be available for sale, too hard to get at or too scattered, or of currently unwanted species or quality. More forest products may be obtained by reducing the "forest capital."

Rotation ages for saw-log trees in extensively managed stands by forest-type and site-index classes

(In years)

| Forest type | | Sit | e index (| 50-year he | eight in fee | et)* | |

| Elm-ash-cottonwood† | | | | 80 | 70 | 60 | 60 |

^{*} Except in the case of cottonwood for which it is total height at 25 years.

Miscellaneous Definitions

Site class. — A classification of commercial-forest land based on potential yields in cubic feet per acre of mean annual growth at culmination of increment in fully stocked stands of desirable trees.

D.b.h. (Diameter at breast height). — Tree diameter in inches measured outside the bark at a point $4\frac{1}{2}$ feet above the ground.

[†] The rotation for cottonwood is half of the age shown.

Statistical Tables

The following tables present forest-resource data for the Southern Cumberland Unit and each of its 12 counties. Tables 1-7 contain information on land and forest area; tables 8-12 information on numbers of trees and timber volume; and tables 13-18 information on growth, cut, and desirable cut. Data for individual counties are shown in tables 1, 4, 10, 14, and 18.

Table 1. -- Area of land and forest land by counties
Southern Cumberland Unit, Kentucky, 1963

| | | | | Forest land | | Commercial forest |
|------------|-------------|------------|------------|--------------------|------------|------------------------------|
| County | Gross area* | Land area* | All forest | Non- commercial | Commercial | as a percent of land area |
| | Acres | Acres | Acres | Acres | Acres | Percent |
| Bell | 236,800 | 236,800 | 211,500 | 12,600 | 198,900 | 84.0 |
| Breathitt | 316,200 | 316,200 | 281,900 | 900 | 281,000 | 88.9 |
| Clay | 303,400 | 303,400 | 247,600 | 400 | 247,200 | 81.5 |
| Estill | 166,400 | 166,400 | 125,700 | 300 | 125,400 | 75.4 |
| Jackson | 215,700 | 215,700 | 161,700 | 500 | 161,200 | 74.7 |
| Knox | 238,700 | 238,700 | 177,700 | 100 | 177,600 | 74.4 |
| Laurel | 286,100 | 283,500 | 189,000 | 1,200 | 187,800 | 66.2 |
| Lee | 134,400 | 134,400 | 109,200 | 200 | 109,000 | 81.1 |
| McCreary | 269,400 | 261,100 | 249,800 | 1,600 | 248,200 | 95.1 |
| Owsley | 126,100 | 126,100 | 96,900 | 100 | 96,800 | 76.8 |
| Rockcastle | 199,000 | 199,000 | 140,500 | 1,100 | 139,400 | 70.1 |
| Whitley | 294,400 | 293,100 | 229,100 | 900 | 228,200 | 77.9 |
| Total | 2,786,600 | 2,774,400 | 2,220,600 | 19,900 | 2,200,700 | 79.3 |

^{*} Gross area and land area are from Bureau of Census, 1960. Land area includes 2,400 acres in small bodies of water.

Table 2. -- Area of commercial-forest land by ownership and stand-size class

Southern Cumberland Unit, Kentucky, 1963

(In acres)

| Ownership class | All stands | Saw- timber | Pole- timber | Seedlings and saplings | Non- stocked |
|----------------------------------|---------------|----------------|-----------------|------------------------------|-----------------|
| National Forest | 306,000 | 246,300 | 53,300 | 2,500 | 3,900 |

THE AUTHORS

DAVID A. GANSNER began his Forest Service career in 1958 at the Lake States Forest Experiment Station, working on the Forest Survey in Missouri and Minnesota. In 1961 he moved to the Central States Station and his present job as Forest Survey Representative. A native of Missouri, Dave received his degree in forestry from the University of Missouri. He is a member of the Society of American Foresters and Xi Sigma Pi (honorary forestry society).

CLARENCE D. CHASE is a veteran of 12 years administrative experience on the National Forests plus 20 years in charge of Forest Survey at the Lake States Forest Experiment Station. Since 1956 he also has planned and supervised the Forest Survey of the Central States. Chase holds a Bachelor of Forestry degree from the University of Minnesota, his native state, and a Master of Forestry degree from Iowa State University. He is a member of the Society of American Foresters, the American Society of Photogrammetry, and Xi Sigma Pi (honorary forestry society).

The Forest Service of the U.S. Department of Agriculture is dedicated to the principle of multiple use management of the Nation's forest resources for sustained yields of wood, water, forage, wildlife, and recreation. Through forestry research, cooperation with the States and private forest owners, and management of the National Forests and National Grasslands, it strives — as directed by Congress—to provide increasingly greater service to a growing Nation.
